## Spectroscopy of $S p(4)$ gauge theory with $\mathrm{n}_{\mathrm{f}}=3$ antisymmetric fermions

Jong-Wan Lee
(Pusan National University)
In collaboration with E. Bennett, D. K. Hong, H. Hsiao, C.-J. D. Lin, B. Lucini, M. Piai and D. Vadacchino

Lattice 2022 @ Bonn, Germany August 10, 2022

## Global symmetry and pNGBs

- Consider $S p(4)$ gauge group +3 two-index antisymmetric Dirac flavors
- Assumed that the global symmetry is broken explicitly by fermion mass and/ or spontaneously by the fermions condensate

$$
S U(6) \longrightarrow S O(6)
$$

- A large coset: 20 pseudo Nambu Goldstone Bosons (pNGBs)
- A natural subgroup of $S U(6)$ is $S U(3)_{L} \times S U(3)_{R}$, where the diagonal component can be embedded in the unbroken subgroup, $S U(3)_{D} \subset S O(6)$

## Motivation

- Relevant to pheno. model buildings for BSM based on $S U(6) / S O(6)$ coset
- Composite Higgs (CH) \& top partial compositeness
G. Ferretti \& T. Karataev, arXiv:1312:5330;
J. Bernard, T. Gherghetta \& T. S. Ray, arXiv:1311.6562

| Coset | HC | $\psi$ | $\chi$ | $-q_{\chi} / q_{\psi}$ | Baryon | Name |
| :---: | :--- | :--- | :--- | :--- | :--- | :---: |
| Lattice |  |  |  |  |  |  |

## Theory space of $S p(4)$

## Lattice action and simulation details

- Lattice formulation with the standard Wilson gauge \& fermion actions

$$
S \equiv \beta \sum_{x} \sum_{\mu<\nu}\left(1-\frac{1}{4} \operatorname{Re} \operatorname{Tr} U_{\mu}(x) U_{\nu}(x+\hat{\mu}) U_{\mu}^{\dagger}(x+\hat{\nu}) U_{\nu}^{\dagger}(x)\right)+a^{4} \sum_{x} \bar{\Psi}_{k}(x) D^{A S} \Psi_{k}(x)
$$

with $\beta=4 N / g^{2}$

- The Wilson-Dirac operator is given by
$D^{A S} \Psi_{k}(x) \equiv\left(4 / a+m_{0}^{a s}\right) \Psi_{k}(x)-\frac{1}{2 a} \sum_{\mu}\left\{\left(1-\gamma_{\mu}\right) U_{\mu}^{A S}(x) \Psi_{k}(x+\hat{\mu})+\left(1+\gamma_{\mu}\right) U_{\mu}^{A S}(x-\hat{\mu}) \Psi_{k}(x-\hat{\mu})\right\}$
where $\left(U_{\mu}^{A S}\right)_{(a b)(c d)}(x) \equiv \operatorname{Tr}\left[\left(e_{A S}^{(a b)}\right)^{\dagger} U_{\mu}(x) e_{A S}^{(c d)} U_{\mu}^{\mathrm{T}}(x)\right]$, with $a<b, c<d$.

$$
U_{\mu}(x)=U_{\mu}^{F}(x) \in S p(4)
$$

- Simulations using (R)HMC algorithms implemented in the HiRep code

## Lattice setup

- $S p(4)$ theory with fermions: Weak and strong coupling regimes are separated by 1 st order phase transition.

$$
\begin{aligned}
& n_{f}=3 \text { AS Sp(4) }: \quad \beta \gtrsim 6.5 \\
& \text { J.-W. Lee et al, Lattice (2018) } 192
\end{aligned}
$$

- Finite volume corrections are statistically negligible if $m_{\mathrm{PS}} L \gtrsim 7.5$.
E. Bennett et al, Lattice (2021) 274
- negative FV contribution can be understood from the NLO corrections in the low-energy chPT.

Bijnens \& Lu (2009)

- Scale setting: Gradient flow method

## Luscher (2010) Luscher \& Wiese (2011)

$$
\hat{a} \equiv a / w_{0} \quad \hat{m} \equiv m^{\text {lat }} w_{0}^{\text {lat }}=m w_{0}
$$

## Interpolating operators and measurements

- Flavor non-singlet spin 0 and 1 mesons, i.e. $i \neq j$

| Label M | Interpolating operator $\mathcal{O}_{\mathrm{M}}$ | Mesons in QCD | $J^{P}$ | $S O(6)$ |
| :---: | :---: | :---: | :---: | :---: |
| PS | $\overline{\Psi^{i}} \gamma_{5} \Psi^{j}$ | $\pi$ | $0^{-}$ | 20 |
| S | $\overline{\Psi^{i}} \Psi^{j}$ | $a_{0}$ | $0^{+}$ | 20 |
| V | $\overline{\Psi^{i}} \gamma_{\mu} \Psi^{j}$ | $\rho$ | $1^{-}$ | 15 |
| T | $\overline{\Psi^{i}} \gamma_{0} \gamma_{\mu} \Psi^{j}$ | $\rho$ | $1^{-}$ | 15 |
| AV | $\overline{\Psi^{i}} \gamma_{5} \gamma_{\mu} \Psi^{j}$ | $a_{1}$ | $1^{+}$ | 20 |
| AT | $\overline{\Psi^{i}} \gamma_{5} \gamma_{0} \gamma_{\mu} \Psi^{j}$ | $b_{1}$ | $1^{+}$ | 15 |

- We use the $Z_{2} x Z_{2}$ single time slice stochastic wall sources with hit number 3
- We extract the mass of the first excited state of vector meson by solving the generalized eigenvalue problem (GEVP) for correlation functions built from two independent interpolating operators.

## List of ensembles

## Numerical results: Gradient flow scale

$$
\begin{aligned}
& E(t)=-\frac{1}{2} \operatorname{Tr}\left(G_{\mu \nu} G_{\mu \nu}\right) \\
& k_{\alpha} t^{2}\langle E(t)\rangle \equiv k_{\alpha} \mathcal{E}(t)
\end{aligned}
$$

$$
\left.\mathcal{E}(t)\right|_{t=t_{0}}=\mathcal{E}_{0}
$$

$$
\left.\mathcal{W}(t)\right|_{t=w_{0}^{2}}=\mathcal{W}_{0}
$$

$$
\text { with } \mathcal{W}(t) \equiv t \frac{\mathrm{~d} \mathcal{E}(t)}{\mathrm{d} t}
$$

| + Plaquette | $I$ | 0.2 | I | 0.35 | I | 0.5 | I | 0.8 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| - | Clover | I | 0.3 | I | 0.4 | I | 0.6 | I |

$\begin{array}{lllllllll}\text { + Plaquette } & \text { I } & 0.2 & \text { I } & 0.35 & \text { I } & 0.5 & \text { I } & 0.8 \\ \text { - Clover } & \text { I } & 0.3 & \text { I } & 0.4 & \text { I } & 0.6 & \text { I } & 1.0\end{array}$

- $w_{0} / a$ is less affected by the lattice artifacts (UV fluctuation)
- GF scales are showing significant mass dependence
- Reference scale is chosen according to a simple $N_{c}$ scaling
E. Bennett et al (2022), arXiv:2205.09364
$\mathcal{W}_{0}=0.28$ for $\operatorname{Sp}(4)$

How far from the massless limit?

## How far from the massless limit?

## Conformal or chirally broken?

- A sign of conformality?

## Conformal or chirally broken?

- A sign of conformality? No!
- indicates that our theory is indeed in the broken phase (as expected)

| Ensemble | Volume | $\beta$ | $a m_{0}$ | $N_{\text {configs }}$ | $\langle P\rangle$ | $w_{0} / a$ |

## Vector meson mass in units of PS decay constant

- related to the coupling $g_{V P P}$ through KSRF relation: $\quad g_{V P P}=\frac{m_{\mathrm{V}}}{\sqrt{2} f_{\mathrm{PS}}}$ Kowarabayashi \& Suzuki (1966) Riazuddin \& Fayyazuddin (1966)
- In the massless limit, it is approaching the value smaller than the one in $\mathrm{N}_{\mathrm{f}}=2(\mathrm{~F}) S p(4)$ theory

Results: first excited state of vector meson

## Massless and continuum extrapolation

- Despite of a long massless extrapolation, we use the following ansatzs linear in $\hat{m}_{\mathrm{PS}}^{2}$ and $\hat{a}$ to fit the data for ensembles in the linear regime.

$$
\begin{aligned}
\hat{m}_{M}^{2, \mathrm{NLO}} & =\hat{m}_{M}^{2, \chi}\left(1+L_{m, M}^{0} \hat{m}_{\mathrm{PS}}^{2}\right)+W_{m, M}^{0} \hat{a} \\
\hat{f}_{M}^{2, \mathrm{NLO}} & =\hat{f}_{M}^{2, \chi}\left(1+L_{f, M}^{0} \hat{m}_{\mathrm{PS}}^{2}\right)+W_{f, M}^{0} \hat{a}
\end{aligned}
$$

- Restrict to the continuum extrapolated results over the mass range of data available as our final results
- Still useful for the phenomenological model buildings for comp. Higgs, top partial compositeness and dark matter - massless limit may not be required

## Results: masses in the continuum limit

## Results: decay constants in the continuum limit

Meson spectrum of $\mathrm{n}_{\mathrm{f}}=3$ AS $S p(4)$

## Conclusion

- $\mathrm{Sp}(4)$ theory with $\mathrm{nf}=3$ antisymmetric fermions is relevant to top-partial compositeness, composite Higgs and dark matter
- We have studied the spectrum of mesons in spin-o and 1 channels including the first excited state of the vector meson - no sign of (near) conformality
- Gradient flow scale shows a large mass dependence, which challenges to getting close to the massless limit
- Continuum extrapolation has been carried out only in the large mass regime using a simple linear ansatz for the PS mass squared and the lattice spacing

Could still be phenomenologically interesting for BSM physics based on new strong dynamics!

Thank you for your attention!
